#### Abstract

Background and Objective The health benefits of regular exercise are well known, and the transition to adulthood is an important time for establishing exercise habits. In this study, we aimed to identify the degree of obesity prevention and fitness according to exercise level in male and female university students who live in dormitories.

## Material and Methods

This study included 1,808 university dormitory residents, 1,263 men and 545 women, who completed a sociodemographic questionnaire and were classified into groups according to exercise habit. Sociodemographic data were expressed as frequency and percent, and one-way analysis of variance was conducted to examine the group difference according to exercise habit.

## Results

Weight, muscle mass, lean body mass, and basal metabolism were significantly higher in male university students living in dormitories who habitually exercise at least 3 times a week compared to those who exercise less often ( $p<0.05$ ). The body mass index was higher in female university students living in dormitories who exercise at least 3 times a week compared to those who exercise less often ( $p<0.05$ ). The former group could also perform a greater number of sit-ups ( $p<0.01$ ) and had greater back strength ( $p<0.01$ ) and faster

[^0]whole-body reaction time ( $p<0.01$ ). Women who exercised at least once a week could perform more pushups versus those who did not exercise ( $p<0.01$ ). Male university students living in dormitory who exercise at least 3 times a week had higher systolic blood pressure and greater grip strength than male students who exercised twice a week or less ( $p<0.05$ ); they could also do more push-ups ( $p<0.05$ ).

## Conclusion

University students who exercise at least 3 times a week have somewhat higher fitness and healthier body composition compared to those who exercise twice a week or less. These differences may impact lifetime fitness and body composition.

University dormitories aid in building self-reliance and the spirit of independence as well as affecting students' daily life, culture, study habits, and preparation for employment. The university dormitory is developing to provide total care for university students.

Entering college at 18-20 years of age is an important period in a young person's life as this experience can help to establish behavioural patterns that could lead to a healthy lifestyle in adulthood and old age. ${ }^{1}$ However, risky health behaviour that could induce overweight and obesity are prevalent in many college students. ${ }^{2}$ It has been reported that students are at highest risk of gaining weight in their junior or freshmen year. ${ }^{3}$ Studies conducted in the United States have shown that students in their junior or freshmen days in university experience higher weight gain than same-aged people who do not attend university. ${ }^{4,5}$ Studies in Europe ${ }^{6,7}$ have reported that a popular name for college weight gain, "freshman 15," was coined due to the myth that first-year university students gain 15 pounds; although the students studied did gain weight over the first year, the typical gain was smaller in reality than in the myth. ${ }^{8,9}$ During freshman year, changes in diet, drinking, and exercise habits can continue to impact students' weight and health over time. ${ }^{10}$ A recent study suggested that this weight gain persists over 4 years, indicating that it may have ramifications later in life. ${ }^{11}$

Many studies regarding the weight gain of freshmen students have been conducted in the United States. However, university culture is highly varied; for example, university students in most European countries live in considerably different circumstances, ${ }^{6,7}$ more often with their parents or in student houses than in dedicated dormitories. Many factors have been found to influence weight gain, including membership in
student groups, which can create a less regular eating schedule; furthermore, students with irregular schedules are also less willing to change their eating habits when encouraged to make healthy choices. ${ }^{12}$

Since cultural influences vary between countries and even between corps students and non-corps students, it is vital to study each population to increase the effectiveness of intervention. This is one of the first studies on weight and fitness in Korean university students.

The physical activity patterns of most college students living in dormitories are not at optimal levels and get worse over time: one third of college students are sedentary and tend to become less physically active throughout their college years. ${ }^{2,13}$ Dormitory living can present considerable heterogeneity in spatial distribution of eating and physical activity locations, which can affect behaviour. Uncontrolled dormitory environments can worsen the health status of university students, but encouraging them to participate in sports and physical activity can prevent those problems.

In general, exercise results in physical and psychological benefits. Regular exercise helps to maintain body weight and prevents metabolic syndromes such as obesity, diabetes and cardiac diseases. ${ }^{14}$ In addition, exercise improves self-esteem, ${ }^{15}$ anxiety, ${ }^{16}$ depression and $\operatorname{mood}^{17}$; therefore, exercise is a critical factor that could affect emotional welfare. Furthermore, exercise improves short-term memory by activating prefrontal and occipital cortexes, indicating that exercise may improve academic achievement in college students. ${ }^{18}$ Therefore, engagement in exercise among first-year university students is the first step to helping students maintain a healthy lifestyle in college and later life. In this study, we aimed to identify the obesity and fitness level of university students living in dormitories

[^1]according to exercise level, therefore providing useful data for promotion of physical activity on campus.

## METHODS

## Participants

We enrolled 1,808 male and female university students who live in dormitories. Students were randomly selected and details regarding their sociodemographic characteristics including exercise habits, life habits, safety consciousness, and health status were collected. Students were classified into groups according to
exercise habit and gender. ${ }^{19}$ The sociodemographic and physical characteristics of the subject are shown in Table 1 and Table 2. Prior to participation in this study, students provided voluntary informed consent. Of 1,808 subjects, $1,263(69.9 \%)$ were male and 545 ( $30.1 \%$ ) were female. Five hundred and 3 men ( $39.8 \%$ ) and 165 women ( $30.3 \%$ ) exercised more than 3 times a week; 230 men ( $18.2 \%$ ) and 96 (17.6\%) women exercised less than twice a week, and 185 men ( $14.6 \%$ ) and 108 women ( $19.8 \%$ ) reported no exercise. Three hundred and forty five men and 176 women did not respond to this question.

TABLE 1 The Sociodemographic Characteristics of the Participants

| Variables | Items |  | $n$ | \% |
| :---: | :---: | :---: | :---: | :---: |
| Sex | Male |  | 1263 | 69.9 |

## Evaluation of Body Composition

The measurement of body composition was conducted according to the recommendations in Applied Body Composition Assessment. ${ }^{20}$ Students were asked to remove any metal objects that they were carrying, and measurements were conducted 30 min after urination and following a 5 minute period of rest. Weight, body mass index (BMI), and percentage of body fat were assessed using a body composition measuring instrument, Inbody 720 (Biospace Co., Seoul, Korea).

## Physical Fitness Tests

Physical fitness was evaluated by conducting tests of aerobic capacity, muscular strength, muscular endurance, flexibility, and agility according to guidelines in Advanced Fitness Assessment and Exercise Prescription. ${ }^{21}$ Aerobic capacity was evaluated using a bicycle ergometer (Aerobike 75XL, Combi Co., Tokyo, Japan). Muscular strength was evaluated based on measurements of back muscle strength and grip strength; muscular endurance was evaluated by measuring the number of sit-ups and push-ups performed in 60 seconds; flexibility was evaluated via a sit and reach test; agility was evaluated by measuring reaction time to auditory stimulus; and power was evaluated by vertical jump using a digital measuring instrument (Helmas $\mathrm{O}_{2}$ Run, Seoul, Korea).

## Statistical Analyses

Male and female students were each divided into 3 groups: students who reported exercising at least 3 times a week (the $3+$ group), students who reported exercising once or twice a week (the $1-2$ group) and students who reported no exercise (the 0 group). Oneway analysis of variance and a Tukey post-hoc test was used to determine differences between groups reporting different exercise habits. Statistical analysis was performed using IBM SPSS Statistics ver. 18.0 (IBM Co., Armonk, NY, USA). The significance level was set at $p<0.05$.

## RESULTS

## Differences in Body Composition According to Exercise Habit among University Students Living in Dormitories

Table 3 shows differences in body composition between groups of dormitory-dwelling university
students. Compared to the other 2 groups, men who exercised more than 3 times a week (the $3+$ group) showed significantly higher weight ( $p<0.05$ ); muscle mass ( $p<0.01$ ); fat-free mass ( $p<0.01$ ); and basal metabolism ( $p<0.01$ ). Women who exercised 3 times a week had higher BMIs than women who exercised less often or not at all ( $p<0.05$ ).

## Difference in Cardiovascular Function and Physical Fitness According to Exercise Habit among University Students Living in Dormitories

Table 4 shows the differences in cardiovascular function and physical fitness between groups. Men in the $3+$ group had higher systolic blood pressure and grip strength (both $p<0.05$ ), and could perform more push-ups ( $p<0.05$ ) compared to men in the other 2 groups.

Women in the $3+$ group could perform more sit-ups ( $p<0.01$ ), had greater back and grip strength (both $p<0.01$ ), and had faster whole-body reaction times $(p<0.01)$ than women in the other 2 groups. Both women who exercised $3+$ times and women who exercised 1-2 times could perform more pushups ( $p<0.01$ ) than women who reported no exercise.

## DISCUSSION

University life is characterized by a time of new found independence through which students become responsible for their own routines, and as such this marks a critical juncture for education and the formation of healthy habits. ${ }^{22}$

Different styles of residences, including boarding houses, dormitories, relatives' houses, and residential houses may affect the lifestyle of university students. Health promotion behaviour that can be affected by these factors may also affect optimal well-being, personal achievement, and productive life. ${ }^{23}$ Furthermore, because university students experience rapid physical, mental, and social development, and experience fewer specific symptoms of ill health, they may be more insensitive to the necessity of health care than older adults. ${ }^{24}$

Maintaining proper fitness is necessary for health promotion and maintenance; cardiorespiratory fitness, especially, is very important for a consistent supply of oxygen and the removal of carbon dioxide and

body wastes. Recently, an inverse relationship was reported between cardiorespiratory fitness and metabolic syndrome. ${ }^{25}$ Obesity, and abdominal obesity per se, induce metabolic syndrome through multiple risk factors including hyperglycemia, hyperlipidemia, and hypertension. ${ }^{26}$ Metabolic syndrome is an important health and social problem, as untreated metabolic syndrome can cause premature death via type 2 diabetes, cardiovascular disease, and stroke. ${ }^{27}$

Exercise has many benefits, including an increase in basal metabolism with increase of energy expenditure and activation of metabolism, ${ }^{28,29}$ a decrease in blood pressure, ${ }^{30}$ and an improvement in cardiorespiratory fitness. ${ }^{31}$

The significantly higher muscle mass, lean body mass, and basal metabolism of participants in the $3+$ group of male students indicates that this cohort has a more healthy body composition, despite their heavier weight.

Although the $3+$ group of female university students had higher BMIs compared to those in the other 2 groups, students in this group were not obese. The incidence of obesity in our study group was lower than that reported in the Korea National Health and Nutrition Examination Survey (2015), which showed a prevalence of $36.5 \%$ and $26.4 \%$ among men and
women, respectively, aged more than 19 years old. It was also lower than that reported by the American National Health and Nutrition Examination Survey (2005-2008), which showed $72.8 \%$ and $63.0 \%$ obesity or over-weight prevalence in mean and women more than 20 years old with $>25 \mathrm{~kg} / \mathrm{m}^{2}$ of BMI, and $32.9 \%$ and $35.6 \%$ obesity prevalence in men and women with $>30 \mathrm{~kg} / \mathrm{m}^{2}$. ${ }^{19}$

Men in the 3+ group had higher systolic blood pressure, but this was still within normal range. In general, blood pressure increases after exercise, and decline of blood pressure is related to vascular compliance. Acute aerobic exercise can have a positive effect on vascular compliance. The $3+$ group's significantly higher push-up and grip strength are likely to result from higher muscle mass and lean body mass that would positively affect muscular function.

Our findings that the $3+$ group of dormitorydwelling women were more fit than the other groups differ with the report that female university students showed no difference in exercise habit or showed decreasing tendency, ${ }^{32}$ but it is assumed that maintaining regular exercise more than 3 times a week can affect health-related fitness. However, it is thought that the reason for decreasing exercise habit in other studies may be due to lack of time, motivation, and

[^2]housework support; this could be partly ameliorated by dormitory life. ${ }^{32}$

In this study, men and women living in dormitories showed significant differences in strength and endurance performance according to exercise habit. Blood pressure and heart rate also differed, although insignificantly, between groups. The development of obesity and metabolic syndrome as a result of changes in cardiorespiratory fitness is not limited to adulthood; prevention of these diseases is also necessary in the adolescent period and during young adulthood and university life.

Although dormitory-dwelling university students may not maintain fitness habits throughout their entire lives, regular exercise habits can have a positive effect on the change of body composition and fitness variables. This study examined the effect of participation in exercise, including intermittent participation, and found that more frequent participation positively correlated with fitness markers.

## CONCLUSION

The higher scores on some fitness tests of university students who exercise at least 3 times a week compared to those who exercise twice a week or less indicate that exercise habits have a strong influence on the fitness of university students, which are likely to persist in later life. Differences in body composition are also evident, although not as pronounced, and may have even greater effects on lifetime health. College students living in dormitories should be encouraged to adopt healthy exercise habits.
